recordings at a single voltage (-50 mV), single-channel conductance was calculated as the reciprocal of resistance, estimated using Ohm's law ($V = i * R$) and assuming a reversal potential of 0 mV.

Mechanical activation of cell-attached patches was achieved by applying a calibrated negative pressure stimulus using a pneumatic transducer (Fluke). In the majority of experiments, -10 mmHg was applied. Pressure stimuli more negative than -15 mmHg typically resulted in instability or complete loss of the seal and were therefore avoided. The minimum recording duration for each cEC was 300 seconds.

Reagents

Yoda1, gadolinium, GSK 1016790A, and GSK 2193874 were purchased from Tocris Bioscience (USA). GsMTx4 was purchased from Alomone Labs. All other chemicals and reagents were obtained from Sigma-Aldrich (USA).

Statistical analysis

Data in figures and text are presented as means \pm standard error of the mean (SEM), unless otherwise stated. All experiments were performed in a randomized manner (animals, pharmacological treatments). Statistical tests were performed using GraphPad Prism 9 software. Since most tests of normality are not powered to detect departures from normality when n is small, non-parametric tests were used for analyses. In particular, statistical significance was determined using Kruskal-Wallis test, Mann Whitney test or Wilcoxon test, as specified in figure legends. *P*-values < 0.05 were considered statistically significant. Blinding procedures were not generally used because of the limited number of groups and the difficulty in adapting them during experiments using specific genotypes, although some imaging data presented in Figure 7 were analyzed in a blinded manner. Animals were excluded from analysis in cases where GCaMP8 expression was low in *Cdh5*-GCaMP8 mice (assessed by the experimenter) or in the event that signal-to-noise ratio was low in Ca^{2+} -imaging experiments. Sample size was estimated based on previous larger samples reported in the literature by our group and others (22, 28, 63).

Data Availability

All study data are included in the article and supporting information.

SUPPLEMENTAL FIGURES

Supplemental Figure 1

Figure S1. Representative images of the entire retina preparation in response to pressure changes. *En face* retina preparation from a *Cdh5*-GCaMP8 mouse shows EC Ca²⁺ transients in response to elevating intravascular pressure at the cannulated ophthalmic artery from 20 to 40 to 60 to 80 and then back to 20 mmHg.

Supplemental Figure 2

retina cECs

Figure S2. Genetic deletion of Piezo1 abolishes Piezo1 activity in retinal capillaries. Scatter plots of open probability (NP₀) of Yoda1-induced channel openings in Piezo1^{EC-KO} and control cECs. Recordings were performed in the cell-attached mode at a holding potential of -50 mV (Piezo1^{EC-KO}, n = 9 cells from 2 mice; Control, n = 12 cells from 2 mice). Black horizontal lines are mean values, and error bars (pink and red) represent SEM (***P* < 0.01, Mann-Whitney test).

Supplemental Figure 3

Figure S3. Representative images of Ca^{2+} signals in a capillary segment focally stimulated with Yoda1. Time course of Ca^{2+} fluorescence in a capillary from a pressurized *Cdh5*-GCaMP8 retinal preparation in response to picospritzing 30 μM Yoda1. The location of the tip of the picospritzing pipette is marked with a red “*”. Focal application of Yoda1 lasted 3 s at a low ejection pressure (<3 psi).

Supplemental Figure 4

Figure S4. Mechano-pharmacologically induced endothelial Ca^{2+} transients are driven by Piezo1 channels. (a) Imaging field of a capillary in a pressurized retina preparation at baseline (40 mmHg; *left*) and after elevating intra-ocular pressure from 40 to 80 mmHg (*right*) showing Ca^{2+} responses in the absence (top; control) and presence (bottom) of focally applied Yoda1 (30 μ M; 30 s exposure, 3 psi). (b) Traces showing Ca^{2+} transients in the target capillary before, during and after the pressure-change sequence (40-to-80-to-40 mmHg) under control conditions (black) or with concurrent focal application of Yoda1 (blue). Conditions are as described in a.

SUPPLEMENTAL MOVIES

Movie S1: Whole *Cdh5*-GCaMP8 retina imaging while changing the intravascular pressure at the ophthalmic artery from 20 to 80 to 20 mmHg. *Left:* control condition; *Middle:* perfusion solution was supplemented with 30 μ M Yoda1; *Right:* perfusion solution was supplemented with Yoda1 and 10 μ M ruthenium red.

Movie S2: Focal stimulation of a capillary segment in a pressurized retina (40 mmHg) with 30 μ M Yoda1. *Green:* Ca^{2+} transients; *Red:* Yoda1 solution supplemented with TRITC-dextran; *Blue:* endothelial cell outline.

Movie S3: Focal stimulation of a capillary segment in an unpressurized retina (0 mmHg) with 30 μ M Yoda1 (as in movie S2).

Movie S4: A change in pressure at the ophthalmic artery of a retina preparation (40 to 80 mmHg) evoked Ca^{2+} transients in a capillary segment.

Movie S5: Similar to Movie S4 in addition to the simultaneous focal application of Yoda1 (30 μ M) onto the capillary of interest.
